

Predicted rate of inbreeding against the number of sires

● predicted ΔF , as coded

One-stage variant of test1: 50 dams, 5 male and 20 female candidates per dam, $p_f = 0.05$, $p_s = M_s / 250$.

Between 19 and 20 sires the selected-fraction adjustment (Bijma and Woolliams 2000, Eq. 13) switches off and the β terms of hyper_correct switch on, so predicted ΔF rises.
