

Truncation selection: the best fraction p of candidates is kept

For $p = 20\%$:

threshold $t = 0.842$

intensity $i = \phi(t)/p = 1.400$

$k = i(i - t) = 0.781$

variance among selected $= 1 - k = 0.219$

The variance reduction k drives the
Bulmer effect.
