

Predicted rate of inbreeding against the number of sires

● as coded: female fractions use $1/M_s$

● alternative: female fractions use $1/M_d$

Female selected fraction $p_f = 0.05$ is below $1/M_s$ for $M_s < 20$, so the choice matters here. With $p_f = 0.2$ (as in the test fixtures) both give the same answer. Note the rise from 19 to 20 sires, where both the adjustment and the extra β terms of `hyper_correct` switch at once.
