

Generation interval from the selected numbers (dams of the ovlpgrp example)

Intended (and now computed):

$$L_d = \sum c \cdot w_c = 1 \times 0.9725 + 2 \times 0.0275 = 1.0275$$

same for sires (all from class 1: $L_s = 1$); $L = (L_s + L_d)/2 = 1.014$

Original code (assignment instead of sum):

$L_d \leftarrow (\text{value left by trunc_delta}) + c^* \cdot w_c^*$ for the last active class c^*
 $= 1.0275 + 2 \times 0.0275 = 1.083$ on these numbers: class 2 counted twice
specified-count mode: trunc_delta never runs, $L_d \leftarrow c^* \cdot w_c^*$ only
